## III. CLAIM AMENDMENTS

1. (Currently amended) A suboptimal method for searching for a symbol sequence, comprising:

determining a channel impulse response;

sampling a received signal;

- selecting at least one of the highest and/or most reliable impulse response values;
- determining a reference signal using the at least one impulse response value and a symbol sequence assumed as transmitted;
- determining differential terms corresponding to the selected impulse response values for the signal a sample of the received signal and the reference signal;
- applying the determined differential terms to a symbol sequence transition metric for searching for a the symbol sequence;
- forming a survivor path by adding the symbol sequence provided by the transition metric to the survivor path formed so far.
- 2. (Original) A method according to claim 1, wherein at least one reference signal is determined using the selected impulse response value and at least one later impulse response value.
- 3. (Original) A method according to claim 1, wherein at least one reference signal is determined using only the selected impulse response value.

- 4. (Currently amended) A method according to claim 1, wherein the a number of differential terms for the transition metric is increased, if when the impulse response comprises a plural number of high and/or most reliable values.
- 5. (Currently amended) A method according to claim 1, wherein the a number of differential terms for the transition metric is decreased, if when the impulse response contains only some high and/or most reliable values or only one high and/or reliable value.
- 6. (Currently amended) A method according to claim 1, wherein the—a highest possible number of differential terms for the transition metric is determined on the basis of the—a length of the channel memory.
- 7. (Currently amended) A method according to claim 1, wherein the a magnitude of the impulse response values is emphasized in the selection of differential terms for the transition metric.
- 8. (Original) A method according to claim 1, wherein the reliability of the impulse response values is emphasized in the selection of the differential terms for the transition metric.
- 9. (Currently amended) A method according to claim 1, wherein the differential term illustrates the a squared Euclidean distance between the received signal sample and the symbol

sequence assumed as transmitted and convoluted with the impulse response values.

- 10. (Currently amended) A method according to claim 1, wherein the differential term illustrates the a squared Hamming distance between the received signal sample and the symbol sequence assumed as transmitted and convoluted with the impulse response values.
- 11. (Currently amended) A method according to claim 1, wherein the differential term illustrates the a correlation between the received signal sample and the symbol sequence assumed as transmitted and convoluted with the impulse response values.
- 12. (Currently amended) A method according to claim 1, wherein the determined transition metric is added to the path metric survivor path formed so far.
- 13. (Original) Computer software according to claim 1, which comprises routines for executing the method steps.
- 14. (Previously presented) A computer memory means according to claim 13, which comprises the computer software.
- 15. (Currently amended) A receiver in which a symbol sequence is searched fort, the receiver comprisesing:

means for determining a channel impulse response, means for sampling a received signal;

- means for selecting at least one of the highest and/or most reliable impulse response values;
- means for determining a reference signal using the at least one impulse response value and a symbol sequence assumed as transmitted;
- means for determining differential terms corresponding to the selected impulse response values for the signal a sample of the received signal and the reference signal;
- means for using the determined differential terms in a transition metric for searching for a the symbol sequence;
- means for forming a survivor path by adding the symbol sequence provided by the transition metric to the survivor path formed so far.
- 16. (Original) A receiver according to claim 15, wherein at least one reference signal is determined using the selected impulse response value and at least one later impulse response value.
- 17. (Original) A receiver according to claim 15, wherein at least one reference signal is determined using only the selected impulse response value.
- 18. (Currently amended) A receiver according to claim 15, wherein the a number of differential terms for the transition metric is increased, if when the impulse response comprises a plural number of high and/or most reliable values.

- 19. (Currently amended) A receiver according to claim 15, wherein the a number of differential terms for the transition metric is decreased, if when the impulse response comprises only some high and/or most reliable values, or only one high and/or most reliable value.
- 20. (Currently amended) A receiver according to claim 15, wherein the a maximum number of differential terms for the transition metric is determined by the a length of the channel memory.
- 21. (Currently amended) A receiver according to claim 15, wherein the a magnitude of the impulse response values is emphasized in the selection of differential terms for the transition metric.
- 22. (Original) A receiver according to claim 15, wherein the reliability of the impulse response values is emphasized in the selection of differential terms for the transition metric.
- 23. (Currently amended) A receiver according to claim 15, wherein the differential term illustrates the a squared Euclidean distance between the received signal sample and the symbol sequence assumed as transmitted and convoluted with the impulse response values.
- 24. (Currently amended) A receiver according to claim 15, wherein the differential term illustrates the <u>a</u> Hamming distance between the received signal sample and the symbol sequence

assumed as transmitted and convoluted with the impulse response values.

- 25. (Currently amended) A receiver according to claim 15, wherein the differential term illustrates the <u>a</u> correlation between the received signal sample and the symbol sequence assumed as transmitted and convoluted with the impulse response values.
- 26. (Currently amended) A receiver according to claim 15, wherein the determined transition metric is added to the path metric—survivor path formed so far.
- 27. (New) A receiver configured to:

determine a channel impulse response;

sample a received signal;

- select at least one of the highest and/or most reliable impulse response values;
- determine a reference signal using the at least one impulse response value and a symbol sequence assumed as transmitted;
- determine differential terms corresponding to the selected impulse response values for a signal sample obtained by sampling the received signal and the reference signal;
- use the determined differential terms in a transition metric for searching for a symbol sequence;
- form a survivor path by adding the symbol sequence provided by the transition metric to the survivor path formed so far.

- 28. (New) A receiver according to claim 27, wherein the maximum number of differential terms for the transition metric is determined by the length of the channel memory.
- 29. (New) A receiver according to claim 27, wherein the differential term illustrates the squared Euclidean distance between the received signal sample and the symbol sequence assumed as transmitted and convoluted with the impulse response values.
- 30. (New) A receiver according to claim 27, wherein the differential term illustrates the Hamming distance between the received signal sample and the symbol sequence assumed as transmitted and convoluted with the impulse response values.
- 31. (New) An apparatus configured to:

determine a channel impulse response;

sample a received signal;

- select at least one of the highest and/or most reliable
  impulse response values;
- determine a reference signal using the at least one impulse response value and a symbol sequence assumed as transmitted;
- determine differential terms corresponding to the selected impulse response values for a signal sample obtained by sampling the received signal and the reference signal;

- use the determined differential terms in a transition metric for searching for a symbol sequence;
- form a survivor path by adding the symbol sequence provided by the transition metric to the survivor path formed so far.
- 32. (New) An apparatus according to claim 31, wherein the maximum number of differential terms for the transition metric is determined by the length of the channel memory.
